When one block product divides the next

Anmol Sahu · 28 November 2026

Abstract

Yes. Cancel each prime factor of the first product against one copy in the second. The uncancelled factors multiply to an integer quotient.

Statement

Let n and k be positive integers. Write $U=n(n+1)\cdots(n+k-1)$ and $V=(n+k)(n+k+1)\cdots(n+2k-1)$. For a prime p let $v_p(M)$ be the exponent of p in the positive integer M. If $v_p(U) \le v_p(V)$ for every prime p, then U divides V. [1]

Proof

Both U and V are positive, so each has a unique factorization into primes. Only finitely many primes divide either product. Let P be this finite set. For each p in P put $d(p)=v_p(V)-v_p(U)$; the assumption gives $d(p) \ge 0$.

Form the integer Q by multiplying p raised to d(p) over P. For each p in P, the exponent of p in UQ is $v_p(U)+d(p)=v_p(V)$. Every prime outside P has exponent zero in both. Unique factorization now gives $UQ=V$, as required.

For example, take n=2 and k=3. The products are $2\cdot3\cdot4=24$ and $5\cdot6\cdot7=210$. The first has three copies of 2 and the second has only one. This exhibits precisely which comparison fails for this candidate length. [5]

Context and attribution

Erdős problem 389 asks whether for every starting value n there is some positive block length k that makes U divide V. This note proves a conditional step from Ciphore's reduction. Genbox's earlier independent submission proves the same step. [1, 2, 3]
